(54) Title: APPARATUS FOR AND A METHOD OF EXPANDING TUBULARS

(57) Abstract: Apparatus for and a method of expanding tubulars, and particularly tubulars or a string of tubulars that have one or more perforated portions and one or more non-perforated portions. In one embodiment, the apparatus (150) includes an inflatable element (e.g. a packer 152) that has a shaft (156) rotatably coupled thereto so that the shaft (156) can rotate relative to the inflatable element (152). An expansion cone (158) is threadedly engaged with a threaded portion (156t) of the shaft (156) so that it moves along the threaded portion (156t) upon rotation of the shaft (156) relative to the cone (158).

1	"Apparatus for and a Method of Expanding Tubulars"
2	
3	The present invention relates to apparatus for and a
4	method of expanding tubulars, and particularly, but
5	not exclusively, to tubulars that include a
6	perforated or slotted portion and a non-perforated
7	portion.
8	
9	The invention can also be used with combination
10	strings that include non-perforated tubulars and
11	slotted or perforated tubulars that are coupled
12	together to form a string.
13	
14	Use of the term "tubulars" or "tubular members"
15	herein will be understood to encompass any tubular
16	or tubular member, such as casing, liner, drill pipe
17	etc, and other such downhole tubulars.
18	
19	It is known to expand tubular members to increase an
20	outer diameter (OD) and/or an inner diameter (ID) of
21	the tubular member. This can be done by radial
22	expansion of the member, where a radial expansion

PCT/GB02/03734

force is applied to a portion of the member to 1 radially expand it. The radial expansion force is 2 typically applied using an inflatable element, such 3 as a packer. 4 5 Alternatively, the tubular member can be expanded by 6 applying a radial expansion force to the member so 7 that it undergoes plastic and/or elastic 8 In this case, the radial expansion deformation. 9 force is typically applied using an expander device, 10 e.g. an expansion cone, which is pushed or pulled 11 through the tubular member. An OD of the expander 12 device is typically the same as or slightly less 13 than the final ID of the expanded tubular member. 14 15 It will be appreciated that use of the terms "radial 16 expansion" or "radially expanded" herein encompasses 17 both of these options. 18 19 The tubular members are typically used to line or 20 case an open borehole, but have other uses as they 21 can be used, for example, to repair damaged portions 22 of casing or liner. 23 24 The tubular members can include slotted or 25 perforated portions where the slots or perforations 26 expand into approximate diamond shapes or the like 27 when the tubular member is radially expanded. The 28 slotted or perforated portions can be used, for 29 example, as a sand screen at or near a payzone of a 30 formation or reservoir to prevent sand and other 31 such contaminants from being mixed with hydrocarbons 32

3

that are recovered from the payzone or reservoir. 1 The slotted or perforated portions can also be used 2 to allow fluids from the payzone or formation to 3 flow into the tubular member so that they can be 4 recovered to the surface. Use of the term 5 "perforated" herein is intended to encompass slots, 6 apertures or the like in the tubular member. 7 8 According to a first aspect of the present 9 invention, there is provided apparatus for expanding 10 a tubular member, the apparatus comprising an 11 expander device that is capable of generating 12 different radial expansion forces to expand 13 respective portions of the tubular member. 14 15 According to a second aspect of the present 16 invention, there is provided a method of expanding a 17 tubular member, the member including first and 18 second portions, the method comprising the steps of 19 running the tubular member into a borehole and 20 radially expanding the first and second portions in 21 the borehole using an expander device, wherein 22 different radial expansion forces are exerted on the 23 first and second portions respectively. 24 25 The tubular member may have separate portions that 26 are radially expandable to different extents. 27 Typically, the respective portions comprise first 28 and second portions. The first portion typically 29 30 includes at least one perforated portion. second portion typically includes at least one non-31 perforated portion. In most preferred embodiments, 32

1	the perforated portion can expand to a greater
2	extent than the non-perforated portion. Typically,
3	the radial expansion force required to expand the
4	perforated portion is less than the radial expansion
5	force required to expand the non-perforated portion.
6	The tubular member may comprise a string of discrete
7	members having perforated and non-perforated
8	portions. The discrete members are typically
9	coupled together by any conventional means, such as
10	welding; screw threads etc.
11	
12	"Perforated" as used herein means that the member is
13	provided with one or more apertures, slots or the
14	like. Typically, a plurality of apertures or slots
15	are provided. It will be appreciated that "non-
16	perforated" as used herein means that the member
17	does not have apertures or slots therein.
18	
19	One embodiment of an expander device comprises an
20	inflatable element having a shaft rotatably attached
21	thereto. The shaft can preferably rotate relative
22	to the inflatable member. A bearing or the like is
23	typically located between the inflatable element and
24	the shaft. The inflatable member typically
25	comprises a packer or the like. At least a portion
26	of the shaft is provided with a screw thread. An
27	expansion cone can be engaged with the screw thread
28	on the shaft. The screw thread on the shaft is
29	typically a low-pitch screw thread, but can be a
30	high-pitch screw thread. The expansion cone is
31	typically capable of longitudinal movement along the

screw thread when the shaft is rotated relative to 1 2 the cone. 3 The screw thread on the shaft can typically provide 4 a gearing effect to the movement of the cone. 5 low-pitch screw thread provides for slower movement 6 of the cone relative to the shaft, and can provide 7 relatively high radial expansion forces but slower 8 movement of the cone. A high-pitch screw thread 9 provides for faster movement of the cone relative to 10 11 the shaft, and can provide relatively lower expansion forces but faster movement of the cone. 12 Thus, the pitch of the screw thread on the shaft can 13 be selected to provide larger or smaller expansion 14 15 forces as required. 16 The inflatable element typically acts as an anchor 17 for expansion of the perforated and/or non-18 Inflation of the inflatable perforated portions. 19 element typically anchors the expander device at a 20 lower end of the non-perforated portion, and can be 21 used to isolate a pulling force that is typically 22 applied to the expanded perforated portion during 23 expansion of the non-perforated portion. 24 anchoring and isolation provided by the inflatable 25 element substantially prevents the perforations in 26 the pre-expanded perforated portion from collapsing 27 during expansion of the non-perforated portions. 28 29 The shaft is typically provided with attachment 30 means (e.g. screw threads and/or a box or pin 31 connection) to facilitate attaching the apparatus to 32

32

6 a drill string, coiled tubing string, wireline or 1 2 The drill string etc. can be used to the like. rotate the shaft relative to the inflatable member. 3 Optionally, the apparatus may include a motor or the 4 5 like to rotate the shaft. It will be appreciated that a motor will not be required to rotate the 6 shaft where it is coupled directly to a drill 7 string. The motor typically comprises a mud motor 8 where the shaft is coupled to a coiled tubing 9 10 string. 11 The shaft can be rotated in the opposite direction 12 relative to the inflatable member to move the cone 13 back down the shaft to its original starting 14 15 position. 16 Alternatively, or additionally, the cone is 17 preferably provided with an engagement means that is 18 capable of engaging the screw thread on the shaft. 19 The cone is preferably provided with a release means 20 that is used to release the engagement means from 21 engagement with the screw thread on the shaft. 22 The engagement means may comprise first and second 23 portions that are provided with screw threads. 24 first and second portions are preferably capable of 25 26 relative movement towards and/or away from one another. The release means may comprise a threaded 27 rod or bolt that couples the first and second 28 portions together. Rotation of the threaded rod or 29 bolt in a first direction typically brings the first 30 and second portions together, whereas rotation of 31

the rod or bolt in a second direction, typically

1	opposite to the first, separates the two portions.		
2	Thus, the cone can be selectively engaged and		
3	disengaged from the screw thread provided on the		
4	shaft. The cone may include a motor or the like to		
5	rotate the threaded rod or bolt to move the portions		
6	towards or away from one another.		
7			
8	The movement of the first and second portions can be		
9	hydraulically or otherwise controlled. For example,		
10	the release means may comprise a hydraulic cylinder		
11	that can be used to move the first and second		
12	portions towards and/or away from one another.		
13			
14	Alternatively, the cone may be provided with a motor		
15	that rotates it in the opposite direction to move		
16	the cone to the opposite end of the screw thread		
17	(i.e. to return it to its original position).		
18			
19	The release mechanism may comprise other mechanisms		
20	e.g. a self-releasing (high angle) or self-holding		
21	(small angle) taper such as a Morse Standard Taper		
22	Shank or collet-type release.		
23			
24	The expansion cone may be steel or ceramic or a		
25	combination of these materials. The cone may also		
26	be of tungsten carbide. The cone is typically		
27	formed from a material that is harder than the		
28	member that it has to expand. It will be		
29	appreciated only the portions of the cone that		
30	contact that contact the member need be of or coated		
31	with the harder material.		
32			

1	The method typically includes the additional steps
2	of providing an expander device comprising an
3	inflatable element having a shaft rotatably attached
4	thereto, wherein at least a portion of the shaft is
5	provided with a screw thread, and an expansion cone
6	that is engaged with the shaft.
7	
8	The method typically includes the additional steps
9	of attaching the expander device to a drill string,
10	coiled tubing string or the like; and inflating the
11	inflatable element to radially expand a portion of
12	the tubular member into contact with a second
13	conduit. The second conduit may be a casing, liner,
14	a formation around the borehole or the like.
15	
16	The method typically includes the additional steps
17	of deflating the inflatable member and pulling or
18	pushing the expander device through the tubular
19	member to radially expand at least a portion thereof
20	to increase its outer diameter and/or its inner
21	diameter.
22	
23	The method typically includes the additional steps
24	of arresting the travel of the expander device when
25	the cone reaches the non-perforated portion (or a
26	relatively in-expansible portion) of the tubular
27	member, inflating the inflatable member and rotating
28	the shaft against the inflatable member. Rotation
29	of the shaft typically causes the cone to move along
30	the screw thread as it is held stationary by contact
31	with an inner surface of the tubular member.
32	•

9

The method typically includes the additional steps 1 of rotating the shaft in the opposite direction to 2 move the cone back along the screw thread. 3 provides a means of returning the cone to its 4 original starting position. 5 6 The method typically includes the additional steps 7 of releasing the engagement means to disengage the 8 cone from the shaft and allowing the cone to travel 9 back down the shaft. 11 The method typically includes the additional steps 12 of deflating the inflatable member and pulling or 13 pushing the expander device through the tubular 14 member to radially expand at least a portion thereof 15 to increase its outer diameter and/or its inner 16 17 diameter. 18 19 Optionally, the expansion cone may be double-sided. In this embodiment, the expansion cone can be used 20 to radially expand the tubular member in both the 21 upward and downward directions. Use of the terms 22 "upward" and "downward" will be understood to relate 23 to a conventional vertical orientation of a 24 borehole. It will be appreciated that the invention 25 can also be used in deviated wells, and the terms 26 "upward" and "downward" are to be construed 27 accordingly, depending upon the orientation of the 28 It will be appreciated that "downward" 29 generally means away from the surface, and "upward" 30 generally means towards the surface. Optionally 31 also, the cone may comprise a plurality of fingers 32

10

that can be moved from a retracted to an expanded 1 2 configuration. 3 A second embodiment of expander device comprises a 4 rotary expansion mechanism and a solid expansion 5 cone located therebelow. The solid expansion cone 6 may be spaced-apart from the rotary expansion 7 mechanism (e.g. by a shaft or the like) or can be 8 integral therewith. The rotary expansion mechanism 9 typically comprises a cage having a plurality of 10 roller bearings attached thereto. The roller 11 bearings are preferably inclined with respect to a 12 longitudinal axis of the mechanism, typically at an 13 angle of around 20°, so that they form an expansion 14 cone on their outer surfaces. Other angles between 15 around 5° and 45° can also be used, although angles 16 outwith this range may also be used. 17 18 preferred angle is around 20°. 19 The solid expansion cone is typically of steel or 20 ceramic, but can be a combination of these. 21 solid expansion cone may also be of tungsten 22 The cone is typically of a material that 23 carbide. is harder than that of the member that is has to 24 It will be appreciated only the portions of 25 the cone that contact that contact the member need 26 be of or coated with the harder material. 27 28 The rotary expansion mechanism may be rotated by 29 rotating the drill string. Alternatively, or 30 additionally, the rotary expansion mechanism may be 31 rotated by passing fluid (e.g. drilling mud) over, 32

1	across or through the expansion mechanism. The			
2	roller bearings of the rotary expansion mechanism			
3	may be attached to a turbine blade that imparts a			
4	rotational force to the roller bearings when fluid			
5	passes through, over or across the blade.			
6				
7	The method typically includes the additional steps			
8	of rotating the rotary expansion mechanism and			
9	pulling or pushing the apparatus through non-			
10	perforated portions of the tubular member to impart			
11	a radial expansion force thereto. The method			
12	typically includes the additional step of pushing or			
13	pulling the solid expansion cone through portions of			
14	the tubular member that are slotted or perforated.			
15				
16	Optionally, the solid cone can be replaced with a			
17	second rotary expansion mechanism.

WO 03/015954

1 Fig. 5 is a cross-sectional view of a stacked 2 formation: Fig. 6 is a cross-sectional view of a portion 3 of a borehole similar to that of Fig. 4; and Fig. 7 is a part cross-sectional view of an 5 6 alternative embodiment of apparatus for 7 expanding tubulars. 8 Referring to the drawings, Fig. 1 shows a first 9 embodiment of a tubular member 10 (e.g. a portion of 10 casing, liner, drill pipe or other such member) that 11 is used to line or case a borehole (not shown). 12 of the term "tubular member" herein will be 13 understood to encompass any tubular member, such as 14 casing, liner, drill pipe etc. 15 16 Member 10 is preferably of a ductile material so 17 that it is capable of being plastically and/or 18 elastically deformed to expand an inner diameter 19 (ID) and/or an outer diameter (OD) thereof. 20 Alternatively, or additionally, tubular member 10 21 may also be capable of radial expansion under the 22 application of a radial expansion force. 23 24 Member 10 includes a perforated or slotted portion 25 12 that is approximately in a central portion of the 26 member 10, and two non-perforated portions 14, 16, 27 one on each side of the perforated portion 12. 28 non-perforated portions 14, 16 typically house 29 attachment means (e.g. screw threads) that can be 30 used to couple the member 10 into a string of other 31 tubular members. The non-perforated portions 14, 16 32

12

PCT/GB02/03734

13

provide a strong and reliable coupling between 1 successive tubular members. 2 3 The perforated portion 12 is typically used as a 4 sand screen at or near a payzone, a formation or a 5 The perforated portion 12 can also be used to 6 facilitate the recovery of hydrocarbons from the 7 payzone, formation or well, as the slots or 8 perforations allow the hydrocarbons to flow into the 9 member 10 so that they can be recovered to the 10 surface (not shown) in a conventional manner. 11 12 Fig. 2 shows an alternative tubular member 20 13 (similar to tubular member 10) that is provided with 14 two axially spaced-apart perforated portions 22, 24, 15 with non-perforated portions 26, 28 at each end, and 16 a further non-perforated portion 30 between the two 17 perforated portions 22, 24. 18 19 Tubular members 10, 20 can be used for many 20 different purposes, and are typically used in a 21 string of similar or other tubular members (not 22 The string generally includes a number of 23 tubular members that are non-perforated with one or 24 more of the members 10, 20 or the like that have 25 perforations. 26 27 For example and with reference to Fig. 4, there is 28 shown a lower portion of a well or borehole that is 29 provided with a casing 50 at a lower end thereof. A 30 liner 52 (typically one or more non-perforated 31 tubular members) is hung off the bottom of the 32

1	casing 50 in a conventional manner. The liner 52 is	
2	used to line a pre-drilled borehole 56 that extends	
3	towards a payzone, formation or well, indicated	
4	generally by 58, from which hydrocarbons can be	
5	recovered.	
6		
7	The liner 52 is "tied back" to the casing 50 in a	
8	conventional manner and can be cemented into place	
9	by filling an annulus between the borehole 56 and an	
10	outer surface of the liner 52 with cement 54.	
11	Thereafter, a perforated member 60 (which could be	
12	either member 10 (Fig. 1) or member 20 (Fig. 2) or	
13	the like) is inserted through casing 50 and liner 52	
14	so that an upper portion 60u of the member 60	
15	overlaps a lower portion 521 of the liner 52, and	
16	the member 60 is then radially expanded, as will be	
17	described.	
18		
19	Referring to Fig. 5, there is shown a cross-	
20	sectional view of a portion of a stacked reservoir	
21	that typically has layers of different materials	
22	that require to be isolated from one another. For	
23	example, the stacked reservoir may have a lower	
24	shingle or shale layer 70, with a sand or reservoir	
25	layer 72 thereabove, a further shingle or shale	
26	layer 74 above the sand or reservoir layer 72, and a	
27	further sand or reservoir layer 76 below a third	
28	shingle or shale layer 78.	
29		
30	The sand or reservoir layers 72, 76 typically	
31	facilitate the recovery of hydrocarbons from the	
22	surrounding formation that can be recovered to the	

15

surface. In the example shown in Fig. 5, tubular 1 member 20 (Fig. 2) can be used to line or case this 2 3 particular portion of the stacked reservoir. The perforated portions 22, 24 are axially aligned with 4 the sand layers 72, 76. The non-perforated portions 5 26, 30, 28 are axially aligned with the shale layers 6 70, 74, 78 respectively, so that they isolate the 7 shale layers 70, 74, 78, whereas the perforated 8 portions 22, 24 act as a sand screen and allow 9 hydrocarbons recovered from the sand or reservoir 10 layers 72, 76 to be recovered to the surface. 11 12 Fig. 6 shows a lower portion of a borehole that is 13 similar to that shown in Fig. 4. A casing 80 is 14 provided at a lower end of the borehole that 15 typically forms a string of such casings that 16 prevent the formation surrounding the borehole from 17 collapsing, and also facilitates the recovery of 18 hydrocarbons to the surface. A liner 82 (e.g. one 19 or more non-perforated tubular members) is hung off 20 the bottom of the casing 80 in a conventional 21 The liner 82 is typically cemented into 22 place by filling an annulus between the borehole 23 (not shown) and an outer surface of the liner 82 24 with cement 84. 25 26 A perforated or slotted member 86 (e.g. member 20 27 (Fig. 2)) is attached at a lower end of the liner 28 The perforated member 86 is tied back to the 29 liner 82 by overlapping the liner 82 and the member 30 86 so that when the member 86 is radially expanded, 31 an outer surface of the member 86 contacts an inner 32

1 surface of the liner 82 to create a junction and a 2 seal, generally designated at 88. 3 4 As with Fig. 5, a lower end of the horizontal 5 borehole has a number of different portions, similar 6 to the stacked reservoir of Fig. 5 but in a 7 generally horizontal configuration. The borehole of Fig. 6 has a first portion 90 from which 8 hydrocarbons may be recovered; a second portion 92 9 10 --from which hydrocarbons cannot be recovered (e.g. shale, shingle or the like); a third portion 94 from 11 12 which hydrocarbons may be recovered; a fourth 13 portion 96 from which hydrocarbons cannot be recovered; and a fifth portion 98 from which 14 hydrocarbons may be recovered. 15 16 17 A combination of non-perforated and perforated. 18 tubular members can be used to line the borehole. 19 In this particular example, the combination 20 comprises perforated portions 102, 106, 110 at the (hydrocarbon producing) portions 90, 94, 98 and non-21 perforated portions 104, 108 at the non-hydrocarbon 22 producing portion 92, 96. 23 24 25 It will be appreciated that the perforated portions 102, 106, 110 of member 86 may comprise tubular 26 27 members 10 (Fig. 1) that have been coupled to non-28 perforated tubulars (e.g. lightweight pipe) 104, 108 29 using screw threads for example. Alternatively, the 30 various portions may comprise a single length with alternate non-perforated and perforated portions, 31 similar to member 20 (Fig. 2). 32

_	
2	The hydrocarbon producing portions 90, 94, 98 allow
3	hydrocarbons to flow into the combination of non-
4	perforated and perforated tubular members (i.e.
5	member 86), into the member 86 and thus they can be
6	recovered to the surface.
7	
8	It will be noted that the members 10, 20, 60, 86 and
9	other combinations of non-perforated and perforated
10	tubular members can be difficult to expand radially
11	because the members include perforated portions and
12	non-perforated portions. The expansion force
13	required to radially expand perforated portions is
14	significantly less than that required to expand non-
15	perforated portions. The higher force exerted on
16	the non-perforated portion can collapse the expanded
17	perforated tubular that is coupled to the non-
18	perforated portion, because the very high force on
19	the non-perforated portion can pull or stretch the
20	perforated portion so that it collapses radially and
21	the perforations close up.
22	•
23	Note that the radial expansion of the members is
24	typically achieved by expanding the member "bottom-
25	up"; that is, the expander device that is used to
26	impart a radial expansion force is pushed or pulled
27	upwardly through the member from the lowest part to
28	be expanded. However, the member can also be
29	expanded top-down, provided that sufficient force
30	can be applied to the expander device by slacking
31	off weight above the device, or hanging off
32	sufficient weight below the expander device.

18

1 2 Fig. 3 shows a first embodiment of apparatus 150 for expanding tubulars, in this embodiment the tubular 3 4 is a combination string of perforated and nonperforated tubulars. 5 6 7 Apparatus 150 includes an inflatable element, such 8 as a packer 152 that is located at a lower end of 9 the apparatus 150. A bearing 154, such as a thrust 10 bearing, is located above the packer 152 and has a 11 shaft 156 rotatably attached to it. The bearing 154 12 allows the shaft 156 to rotate whilst the packer 152 remains stationary. Shaft 156 is part threaded, 13 preferably with a relatively low-pitch screw thread 14 15 156t, and an expansion cone 158 engages with the 16 screw thread 156t on the shaft 156, the cone 158 17 being capable of longitudinal movement up and down 18 the threaded portion of the shaft 156. A drive 19 means 160 (e.g. a motor or the like) for rotating 20 the shaft 156 is optionally provided at an upper end 21 of the shaft 156. An upper end of the drive means 22 160 is typically attached to a drill string, coiled 23 tubing string or the like. 24 25 It will be appreciated that the drive means 160 may 26 not be required where the shaft 156 is coupled 27 directly to a drill string, as the string can be 28 rotated in a conventional manner to rotate the shaft In this case, the shaft 156 would be provided 29 30 with attachment means (e.g. screw threads) so that it can be attached to the drill string. 31

19

In use, the apparatus 150 is located in a liner 162, 1 casing or the like that is to be radially expanded 2 to increase its outer diameter (OD) and/or inner 3 The packer 152 and the expansion diameter (ID). 4 cone 158 are located in a pre-expanded portion 162e 5 of the liner 162 before the liner 162 is run into 6 the borehole to the required depth. The pre-7 expanded portion 162e is typically sufficiently 8 expanded to allow the packer 152 to be located 9 therein, but is generally not fully expanded so that 10 the liner 162 can be run into the borehole. 11 12 Once at the required depth, the packer 152 is 13 inflated using any conventional means to expand the 14 pre-expanded portion 162e radially outwards so that 15 an outer surface of the pre-expanded portion 162e 16 contacts an inner surface of a second conduit. 17 second conduit may be an uncased formation, pre-18 installed casing, liner, or the like. The further 19 expansion of the pre-expanded portion 162e can act 20 as an anchor for the liner 162 as it is radially 21 22 expanded by the cone 158. 23 Optionally, the packer 152 may be deflated and moved 24 within the liner 162, where it is re-inflated to 25 radially expand the liner 162 into contact with the 26 second conduit. The additional expansion of the 27 liner 162 serves to increase the surface area of the 28 outer surface of the liner 162 that acts as an 29 30 anchor.

20

The packer 152 is then deflated and the cone 158 is 1 pulled through the liner 162 to radially expand the 2 liner 162 in a known manner. The cone 158 may be 3 pulled through the liner 162 using the drill string, 4 coiled tubing string or the like to which it is 5 attached. When the cone 158 reaches a nonperforated portion of the liner 162, this will be 7 indicated by an increase in the force required to 8 expand the liner 162. At this point, the packer 152 9 is re-inflated to act as an anchor for the apparatus 10 Thereafter, the shaft 156 is rotated by 11 actuation of the motor 160, or by rotation of the 12 drill string to which shaft 156 is attached. 13 shaft 156 is thus rotated against the packer 152 14 using the bearing 154. 15 16 It will be appreciated that the packer 152 can be 17 detached from the shaft 156 and left at the lower 18 end of the liner 162 to act as an anchor during 19 expansion of the liner 162. When the cone 158 20 reaches a non-perforated portion, the cone 158 and 21 shaft 156 are lowered until the packer 152 engages 22 the shaft 156, and the apparatus 150 returned to the 23 non-perforated portion, where the packer 152 is re-24 25 inflated. 26 The cone 158 is located on the low-pitch screw 27 thread 156t on the shaft 156 and is prevented from 28 rotating with the shaft 156 by friction on its OD 29 where the cone 158 contacts the liner 162. As the 30 cone 158 is prevented from rotating by contact with 31 the liner 162, it will move up the screw thread on 32

21

shaft 156 as the shaft 156 rotates, and thus expand 1 the liner 162 over the non-perforated portion. 2 3 It will be appreciated that it is preferable to have 4 the length of the portion of the shaft 156 that is 5 provided with the screw thread 156t at least as long 6 as the non-perforated portion of the liner 162. 7 is preferable to have the length of the screw thread 8 156t slightly longer than that required to expand 9 the non-perforated portion. The packer 152 acts as 10 both an anchor for the expansion of the non-11 perforated portion and can also help prevent the 12 expanded perforated portion therebelow from 13 collapsing by keeping it open against the induced 14 collapsing force. 15 16 Once the cone 158 has travelled the length of the 17 screw thread 156t, the shaft 156 can be rotated in 18 19 the opposite direction or the force preventing the cone 158 from rotating is removed, allowing the cone 20 158 to travel back down the screw thread 156t to its 21 original starting position. 22 23 The cone 158 can typically be provided with at least 24 a portion of screw thread that interengages with the 25 thread 156t on the shaft 156. The thread on the 26 cone 158 could be provided on two or more segments 27 that are capable of being moved towards and away 28 from one another. For example, two portions may be 29 coupled using a threaded shaft (e.g. a bolt) that 30 can be rotated to move the two portions towards and 31 away from one another. One of the portions could be 32

provided with a threaded nut that interengages with 1 the threads on the bolt. The threaded bolt may also 2 be provided with a quick-release mechanism, such as 3 a lever that is moved to disengage the nut from the 4 This arrangement is similar to that used in a 5 common bench vice. 6 7 In use, the bolt may be driven by a motor located 8 within or as part of the cone 158. Rotation of the 9 bolt in a first direction would draw the two 10 portions together and thus the cone 158 would be 11 threadedly engaged with the shaft 156. Rotation of 12 the bolt in a second direction, typically opposite 13 to the first direction, would move the two portions 14 away from one another, thus releasing the cone 158 15 from the shaft 156 and allowing it to travel back to 16 its original starting position without rotation 17 (e.g. under the force of gravity or as the shaft 156 18 is pulled out of the borehole). 19 20 Alternatively, the two portions may be coupled using 21 a hydraulic cylinder or the like that can be 22 actuated and de-actuated to move the portions 23 towards and away from one another. 24 25 As a further alternative, other release mechanisms 26 could be used including a self-releasing (high 27 angle) or self-holding (small angle) taper such as a 28 Morse Standard Taper Shank or collet-type release. 29 30 With the cone 158 back in its original position, it 31 can be pulled through the perforated portion until a 32

23

non-perforated portion is reached, whereupon the 1 packer 152 is then inflated and the shaft 156 2 rotated to move the cone 158 through the liner to 3 expand it, as previously described. 4 5 The cone 158 may be double-sided, that is, the cone 6 158 can be provided with a face that can be used to 7 expand the liner or the like in both upward and 8 downward directions. Also, two packers 152 could be 9 used; one that travels with the cone 158 as described above, and a second that is used to anchor 11 the liner 162 at a lower end thereof continuously 12 whilst the remainder of the liner 162 is radially 13 expanded, as described above. 14 15 It would be advantageous to have a segmented cone 16 that is provided with a plurality of fingers that 17 are capable of being moved from a retracted 18 19 configuration to an expanded configuration. Outer surfaces of the fingers can provide one or more 20 21 expansion cones so that when the fingers are in the expanded position, the cone can be used to radially 22 expand the liner 162. However, the cone can be run 23 into the borehole, liner etc in a collapsed state 24 (i.e. with the fingers retracted). 25 advantageous as the liner 162 need not be provided 26 27 with a pre-expanded portion 162e, and the apparatus 150 can be run into a liner that has previously been 28 located in the borehole. The fingers of the cone 29 can then be moved to the radially expanded position 30 so that the liner or the like can be expanded. 31

24

It will be noted that where an expandable cone is 1 used, the packer 152 can be used to inflate a lower 2 portion of the liner 162 (i.e. at the pre-expanded 3 portion 162e) to provide an anchor for the liner 4 Thereafter, the packer 152 is deflated and 5 moved upwardly to a second position, above the 6 first, and inflated again. The second expanded 7 portion of liner 162 facilitates opening of the 8 fingers of the cone more easily into the expanded 9 configuration. 10 11 Referring to Fig. 7, there is shown an alternative 12 apparatus 200 for the radial expansion of a mixed 13 string of perforated and non-perforated tubulars. 14 15 Apparatus 200 is particularly suited for use when 16 expanding portions of non-perforated tubular 202 and 17 perforated or slotted tubular 204. It will be 18 generally appreciated that tubulars 202, 204 may be 19 casing, liner or the like. It will also be 20 appreciated that tubular 202, 204 may comprise a 21 plurality of discrete lengths of tubular member that 22 are coupled together (e.g. by welding or screw 23 24 threads). 25 Apparatus 200 includes a rotary expansion mechanism 26 206 that typically comprises a cage 208 having a 27 number of roller bearings 210 attached thereto. The 28 roller bearings 210 are inclined (typically at 29 around 20° with respect to a longitudinal axis of 30 the apparatus 200) so that they form an expansion 31 cone on their outer surfaces. Other angles between 32

25

around 5° and 45° can also be used, although angles 1 outwith this range may also be used. However, the 2 preferred angle is around 20°. 3 4 The rotary expansion mechanism 206 is primarily used 5 to transmit radial and pull force into a radial 6 expansion force, instead of only pull force. Thus, 7 the rotary expansion mechanism 206 has the advantage 8 of reducing friction. 9 10 An upper portion of the rotary expansion mechanism 11 206 is typically provided with attachment means (not 12 shown) such as screw threads or the like to enable 13 the apparatus 200 to be attached to a drill string, 14 coiled tubing string or the like. 15 16 A solid expansion cone 212 is attached below the 17 rotary expansion mechanism 206, typically via a 18 shaft 214 or the like. It will be understood that 19 the solid expansion cone 212 may be integral with 20 the rotary expansion mechanism 206. The solid 21 expansion cone 212 is typically of steel or ceramic, 22 but may be a combination of steel and ceramic, 23 although it may also be made of tungsten carbide or 24 the like. The solid expansion cone 212 is typically 25 of a material that is harder than the member that it 26 has to expand. As before, only the portion of the 27 cone 212 that come into contact with the tubulars 28 202, 204 need be of or coated with the harder 29 30 material.

1	The perforated or slotted tubular 202 is provided
2	with a pre-expanded portion 202e in which a portion
3	of the apparatus 200 (typically the solid expansion
4	cone 212) is located. Similarly, the non-perforated
5	tubular 204 is provided with a pre-expanded portion
6	204e that is attached to pre-expanded portion 202e
7	in use. Tubulars 202 and 204 can be coupled
8	together using any conventional means, such as screw
9	threads or the like. Conventional pin and box
10	connections may be used, for example.
11	•
12	In use, the slotted or perforated tubular 202 is
13	lowered into the borehole (not shown) to the
14	required depth, and may be held in place using any
15	conventional means (e.g. a packer or the like) if
16	required. Thereafter, the apparatus 200 is attached
17	to a string 216 of drill pipe or the like that forms
18	a conventional drill string. The apparatus 200 is
19	attached to the drill string 216 using any
20	conventional means. It will be appreciated that
21	apparatus 200 could also be attached to a coiled
22	tubing string or the like.
23	
24	The drill string 216 with the apparatus 200 attached
25	thereto is then lowered into the borehole until the
26	solid expansion cone 212 is located within the pre-
27	expanded portion 202e of the perforated or slotted
28	tubular 202. The non-perforated tubular 204 is then
29	lowered into the borehole and the pre-expanded
30	portion 204e is threadedly engaged with the pre-
31	expanded portion 202e of the perforated or slotted
32	tubular 202.

_	
2	It will be appreciated that the apparatus 200 can be
3	located in the pre-expanded portions 202e, 204e and
4	the tubulars 202, 204 threadedly coupled at the
5	surface so that the entire assembly can be lowered
6	into the borehole.
7	*
8	The rotary expansion mechanism 206 is then rotated,
9	typically by rotating the drill string 216. Where
L O [.]	the apparatus 200 is coupled to a coiled tubing
11	string, a mud motor or the like (not shown)
L2	typically forms part of the string and can be used
L3	to rotate the apparatus 200 by actuation of the
L 4	motor. The rotary expansion mechanism 206 may also
L5	be rotated by the flow of drilling fluid (e.g. mud)
L6	through, over or across the mechanism 206. For
L7	example, the rotary expansion mechanism 206 may be
18	provided with a turbine blade (not shown) that is
L9	coupled to the rotary bearings 210 so that drilling
20	fluid that passes over the turbine blades imparts a
21	rotational force to the rotary bearings 210.
22	
23	As the rotary expansion mechanism 206 is rotated, it
24	is pulled upwards through the non-perforated tubular
25	204 to radially expand it. The inclination of the
26	roller bearings 210 of the rotary expansion
27	mechanism 206 provides an expansion force that
28	causes a radial plastic deformation of the non-
29	perforated tubular 204 to radially expand its outer
30	diameter and/or its inner diameter. It will be
31	appreciated that use of the term "radial plastic
32	deformation" is understood to be the use of an

_	expander device (e.g. the rotary expansion mechanism
2	206 or cone 212) that is pushed or pulled through
3	the tubular 204 to impart a radial expansion force
4	to the tubular 204 so that both the ID and the OD of
5	the tubular 204 increases.
6	
7	Once the non-perforated tubular 204 has been
8	completely expanded, the drill string 216 is then
9	lowered until the solid cone 212 contacts the
10	perforated or slotted tubular 202. The cone 212 is
11	then forced through the perforated or slotted
12	tubular 202 by, for example, slacking off weight
13	above the apparatus 200 so that the weight of the
14	string 216 and the apparatus 200 is used to push
15	down on the cone 212. In this way, the tubular 202
16	is radially expanded to increase its OD and its ID.
17	
18	It will be appreciated that the drill string 216 may
19	be rotated, or the apparatus 200 otherwise rotated,
20	so that the cone 212 rotates during use.
21	
22	After the perforated or slotted tubular 202 has been
23	expanded, the drill string 216 and the apparatus 200
24	is then removed from the borehole in the
25	conventional manner (e.g. it is pulled out of hole).
26	
27	It will be appreciated that the solid cone 212 can
28	be replaced with another rotary expansion mechanism
29	206 that can be used to expand the slotted or
30	perforated tubular 202. Where the combination
31	string comprises a single length of non-perforated
32	tubular above a single length of perforated or

slotted tubular, the rotary expansion mechanism 206 1 can be used for upward expansion of the non-2 perforated tubular, and a solid come 212 used for 3 the downward expansion of the perforated or non-4 perforated tubular. Alternatively, a solid cone 5 6 (e.g. cone 212) can be used to expand both. multiple lengths of non-perforated and perforated or 7 slotted tubular, it is preferable to use a rotary 8 expansion mechanism 206 for expansion in both the 9 upward and downward directions. ..10 11 It is possible that expanding a slotted tubular that 12 has non-perforated portions can be done with the 13 The slotted portion can be member in compression. 14 expanded in this situation and it is possible that 15 the expansion force could increase by a factor of 10 16 or more at the non-perforated portions without 17 damaging the expanded perforated portion. 18 19 Certain embodiments of the apparatus and method 20 allow the radial expansion of a combination string 21 of both perforated or slotted tubulars. Certain 22 embodiments also allow the combination string to be 23 radially expanded in only a single pass of the 24 apparatus through the combination string, thus 25 providing significant savings in terms of costs and 26 27 rig time. 28 Modifications and improvements may be made to the 29 foregoing without departing from the scope of the 30 present invention. 31 32

30

1 CLAIMS 2 3 Apparatus for expanding a tubular member 4 comprising an expander device (150, 200) that is 5 capable of generating different radial expansion 6 forces to expand respective portions (12, 14, 16, 7 22, 24, 26, 28, 30, 102, 104, 106, 108, 110) of the 8 tubular member (10, 20, 60, 86, 162, 202, 204). 9 10. 2. Apparatus according to claim 1, wherein the 11 expander device (150, 200) includes an expansion 12 cone (158, 206, 212). 13 14 Apparatus according to claim 2, wherein the 15 expander device (150) further includes an inflatable 16 element (152) having a shaft (156) rotatably 17 attached thereto. 18 19 4. Apparatus according to claim 3, wherein the 20 shaft (156) can rotate relative to the inflatable 21 member (152).

22

Apparatus according to claim 3 or claim 4, 23 5.

24 wherein the inflatable member comprises a packer

25 (152).

26

27 Apparatus according to any one of claims 3 to 6.

28 5, wherein at least a portion of the shaft (156) is

29 provided with a screw thread (156t).

31

Apparatus according to claim 6, wherein the 1 7. expansion cone (158) can engage the screw thread 2 (156t) on the shaft (156). 3 4 Apparatus according to claim 7, wherein the 8. 5 screw thread (156t) on the shaft (156) is a low-6 pitch screw thread (156t). 7 8 Apparatus according to claim 7 or claim 8, 9 9. wherein the expansion cone (158) is capable of ... 10 longitudinal movement along the screw thread (156t) 11 when the shaft (156) is rotated relative to the cone 12 13 (158).14 Apparatus according to any one of claims 3 to 15 9, wherein the inflatable element (152) acts as an 16 anchor for expansion of perforated and/or non-17 perforated portions (12, 14, 16, 22, 24, 26, 28, 30, 18 102, 104, 106, 108, 110) of the tubular member (10, 19 20, 60, 86, 162, 202, 204). 20 21 Apparatus according to any one of claims 3 to 22 10, wherein the inflatable element (152) isolates a 23 pulling force applied to an expanded perforated 24 portion (12, 22, 24, 102, 106, 110) during expansion 25 of a non-perforated portion (14, 16, 26, 28, 30, 26 104, 108) of the tubular member (10, 20, 60, 86, 27 162, 202, 204). 28

29

Apparatus according to claim 1, wherein the 30

expander device (200) comprises a rotary expansion 31

mechanism (206) and a solid expansion cone (212) 1 2 attached thereto. 3 Apparatus according to claim 12, wherein the 4 rotary expansion mechanism (206) comprises a cage 5 (208) having a plurality of roller bearings (210) 6 attached thereto. 7 Apparatus according to claim 13, wherein the 9 roller bearings (210) are inclined with respect to a 10 longitudinal axis of the mechanism (206) so that 11 they form an expansion cone on their outer surfaces. 12 13 Apparatus according to claim 14, wherein the 14 roller bearings (210) are inclined at an angle of 15 around 20°. 16 17 Apparatus according to any one of claims 12 to 18 15, wherein the rotary expansion mechanism (206) is 19 rotatable. 20 21 17. Apparatus according to claim 16, wherein the 22 rotary expansion mechanism (206) is rotatable by 23 rotating a drill string (216), or by passing fluid 24 over, across or through the expansion mechanism 25 26 (206). 27 Apparatus according to any preceding claim, 28 wherein the respective portions comprise first and 29 second portions (12, 14, 16, 22, 24, 26, 28, 30, 30

31 32 102, 104, 106, 108, 110).

Apparatus according to claim 18, wherein the 1 first portion includes at least one perforated 2 portion (12, 22, 24, 102, 106, 110), and the second 3 portion includes at least one non-perforated portion 4 (14, 16, 26, 28, 30, 104, 108). 5 6 Apparatus according to any preceding claim, 7 20. wherein the tubular member (10, 20, 60, 86, 162, 8 202, 204) comprises a string of discrete members 9 having perforated (12, 22, 24, 102, 106, 110) and non-perforated portions (14, 16, 26, 28, 30, 104, 11 12 108). 13 21. A method of expanding a tubular member, the 14 member including first and second portions (12, 14, 15 16, 22, 24, 26, 28, 30, 102, 104, 106, 108, 110), 16 the method comprising the steps of running the 17 tubular member (10, 20, 60, 86, 162, 202, 204) into 18 a borehole and radially expanding the first and 19 second portions (12, 14, 16, 22, 24, 26, 28, 30, 20 102, 104, 106, 108, 110) in the borehole using an 21 expander device (150, 200), wherein different radial 22 expansion forces are exerted on the first and second 23 portions (12, 14, 16, 22, 24, 26, 28, 30, 102, 104, 24 106, 108, 110) respectively. 25 26 A method according to claim 21, wherein the 27 22. method includes the additional step of providing an 28 expander device (150) comprising an inflatable 29 element (152) having a shaft (156) rotatably 30 attached thereto, wherein at least a portion of the 31

shaft (156) is provided with a screw thread (156t),

34

and an expansion cone (158) that is engaged with the 1 2 shaft (156). 3 A method according to claim 22, wherein the 4 method includes the additional steps of attaching 5 the expander device (150) to a drill string or 6 coiled tubing string, and inflating the inflatable 7 element (156) to radially expand a portion (162e) of 8 the tubular member (162) into contact with a second 9 conduit. 10 11 A method according to claim 23, wherein the 12 method includes the additional steps of deflating 13 14 the inflatable member (152) and pulling or pushing the expander device (158) through the tubular member 15 (162) to radially expand at least a portion thereof 16 to increase its outer diameter and/or it inner 17 diameter. 18 19 A method according to claim 24, wherein the 20 first portion comprises one or more perforated 21 portions (12, 22, 24, 102, 106, 110), the second 22 portion comprises one or more non-perforated 23 portions (14, 16, 26, 28, 30, 104, 108), and the 24 25 method includes the additional steps of arresting 26 the travel of the expander device when the cone reaches the second portion (14, 16, 26, 28, 30, 104, 27 108) of the tubular member (162), inflating the 28 29 inflatable member (152) and rotating the shaft (156)

against the inflatable member (152).

35

A method according to claim 25, wherein 1 rotation of the shaft (152) causes the cone (158) to 2 move along the screw thread (156t) as it is held 3 stationary by contact with an inner surface of the 4 tubular member (162). 5 6 A method according to claim 25 or claim 26, 7 27. wherein the method includes the additional step of 8 rotating the shaft (156) in the opposite direction 9 to move the cone (158) back along the screw thread 10 11 (156t). 12 A method according to claim 27, wherein the 13 method includes the additional steps of deflating 14 the inflatable member (156) and pulling or pushing 15 the expander device (150) through the tubular member 16 (152) to radially expand at least a portion thereof 17 to increase its outer diameter and/or its inner 18 19 diameter. 20 A method according to claim 21, wherein the 21 method typically the additional steps of providing 22 an expander device (200) comprising a rotary 23 expansion mechanism (206) and a solid expansion cone 24 (212).25 26 A method according to claim 29, wherein a first 27 tubular member (202) includes one or more perforated 28 portions, a second tubular member (204) includes one 29 or more non-perforated portions, and the method 30 includes the additional steps of rotating the rotary 31 expansion mechanism (206) and pulling or pushing the 32

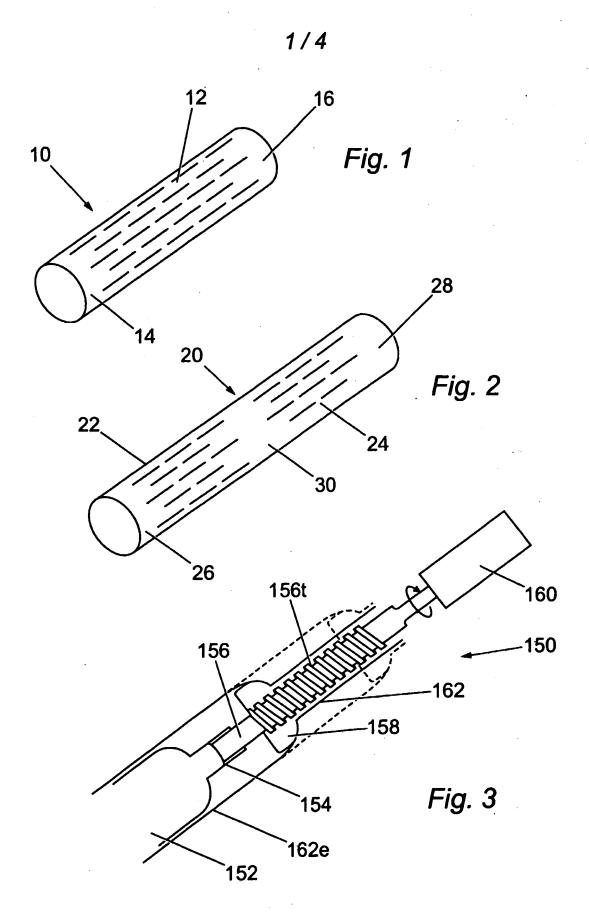

36

device (200) through the second tubular (204) to impart a radial expansion force thereto.

3

4 31. A method according to claim 30, wherein the method includes the additional step of pushing or pulling the solid expansion cone (212) through the

7 second tubular member (202).
